Abstract:

The study investigated the toxic effects of silver on the kidneys and liver of Sprague-Dawley rats after administering multiple doses of silver nanoparticles synthesized using extracts of *Cinnamomum cassia* (CcAgNPs). Twenty-four Sprague-Dawley rats (250 ± 20 g) were randomly assigned into four groups (A-D) of six animals per group and treated for eight weeks. Group A was administered with 200 mg/kg of *Cinnamon Cassia* extracts (Cc), group B with 5 mg/kg of CcAgNPs; group C with 10 mg/kg of CcAgNPs and D with normal saline. Body weight was measured weekly and fasting blood glucose (FBG) was measured fortnightly. At the end of the experiment, animals were euthanized and organs (liver/kidneys) fixed in neutral buffered formalin and processed for light microscopy (H & E). Body weight differences were significantly higher (P < 0.05) in low dose Cc group and the kidney to body weight ratio was not significant. Renal function analysis of proteins and ketones showed a significant increase in CcAgNPs treated rats (P < 0.05). Kidney and liver
histology showed distortions in hepatocytes and sinusoidal linings with infiltrations especially in the higher dose groups. Kidney histology mirrored degenerative changes in glomerular and Bowmans’s capsule with fibrillary mesangial interstitium. CcAgNPs impairs renal and hepatic morphology and function after a long period of administration.

**Keywords:** Histology, nanomedicine, toxicity, degenerative, congestion

1. Introduction

Silver nanoparticles (AgNPs) has gained unique awareness because of their attractive properties, including their high surface to volume proportions, reactant properties and antimicrobial impact (Okafor et al., 2013). This is particularly relevant in the health sciences as it opens new frontiers in drug synthesis and delivery needed to target some of the sanctuary sites difficult for normal therapeutic doses of drugs to penetrate (Peter et al., 2018). However, most techniques used for the synthesis of nanoparticles (NPs) are costly and may negatively influence biological systems. Therefore, green synthesis using plant materials offers a relatively more secure and eco-friendly methodology for NP synthesis and has been readily adopted for silver nanomaterials. Plants offer a completely attractive system for NP synthesis because of their capacity to deliver an extensive variety of optional metabolites with weak potential for toxicity. Plant extracts offer less biohazard, environment-friendly and are less delicate to handle, compared to microscopic organisms and therefore offer a green option for the biosynthesis e.g., AgNPs (Pandey et al., 2013). Pertinent to mention that some plants are already been exploited in this technique for green nanoparticle synthesis including the leaf of Olea europea and the bark of the Cinnamomum zeylanicum tree, used as a part of conventional prescription in Turkey and in different nations (Kumar et al., 2013).

* Cinnamomum cassia, also known as Chinese cassia or Chinese cinnamon, is an evergreen tree originating from southern China and widely cultivated there and elsewhere in
southern and eastern Asia (India, Indonesia, Laos, Malaysia, Taiwan, Thailand, and Vietnam). In South Africa, mostly in KwaZulu Natal region, it is used as a spice and for medicinal remedy in various illnesses, such as diabetes. Lee (2002) had earlier reported this antidiabetic property \textit{in vitro}. \textit{Cinnamomum cassia} extracts offers additional qualities for use in NP synthesis due to the phyto-constituents (phenolics and flavonoids) which act as capping agents providing stability to Ag nanoparticles with the ability to control the size and shape of NPs by giving extra layers to them (Ahmed et al., 2016).

Plant-based AgNPs utilisation in medicine and pharmaceutical interventions may become the way to go owing to the availability, non-toxicity, multi-targeting mechanism of action and variety of metabolites that facilitate reduction of Ag ions in biological systems (Webster et al., 1992). \textit{Cinnamomum cassia} AgNP have been reported to be less toxic and also enhanced antiviral activity against H7N3 influenza A virus (Fatima et al., 2016). However, Yun et al. (2018) in a recent study revealed that high-dose intake of cinnamon extract (2000 mg/kg) showed potential nephrotoxicity and hepatotoxicity to both males and females as evidenced by obvious increases of kidney/liver weight along with a small but statistically elevation of total cholesterol level.

But the study by Shakeel et al. (2018) opined that cinnamon extracts showed significant ameliorative role on the antioxidant system in response to elevated levels of titanium dioxide nanoparticles or titanium dioxide bulk salt-induced oxidative stress with recovery of the antioxidant system as well as histological damages and some haematological parameters in the rat liver treated with titanium dioxide nanoparticles or titanium dioxide bulk salt. There is therefore no concurrence with respect to the safety of AgNPs or its conjugates (Conor et al., 2005; Khlebtsov and Dykman, 2011) warranting further investigations.
Our laboratory has utilised various animal models to demonstrate potential interactions of plant-based adjuvants in many therapeutic conditions for diabetes [Ismail, 2017 #71], hypertension [Azu, 2015 #73] and alcohol-induced antiretroviral toxicity [Ogedengbe, 2018 #72] exploring various markers for biochemical, immunological and histo-morphometric studies. The aim of this study was to evaluate and report the histopathological and biochemical effects of CcAgNPs in male Sprague-Dawley rats after multiple oral administration.

2. Materials and methods

2.1 Collection of plant material

Pure *Cinnamomum cassia* powder was purchased from Warren Chemistry Specialities (Pty) Ltd, CAPE TOWN (reference 492733), during winter break and silver nitrate (AgNO₃) was obtained from Capital Laboratory (Pty), Kwazulu Natal.

2.2 Preparation of *Cinnamomum cassia* (Cc) aqueous plant extracts

For the preparation of *C. cassia* aqueous extracts, approximately 10 g of the powdered plant material (bark) was added to 300 mL of double distilled water and allowed to boil for 10 minutes at 45°C according to the method of Shankar et al. (2017). The resulting mixture was filtered and stored in a refrigerator at 4 ºC until analyzed.

2.3 Synthesis of *Cinnamomum cassia* silver nanoparticles (CcAgNPs)
AgNO₃ was added to C. cassia extract (100 mL) to form the silver nanoparticles (AgNPs) (Ali et al., 2016; Elobeid, 2016). The formation of AgNPs is observed by a change of colour (Shankar et al., 2015).

### 2.4 Structural analysis of Cinnamomum cassia silver nanoparticles (CcAgNPs)

Figure 1a shows the ultraviolet-visible (UV–Vis) spectra of CcAgNPs which is in line with previous results that reported that the UV–Vis absorption spectrum with a distinct peak at 445 nm indicated a surface plasmon resonance for AgNPs, ranging from 2 to 100 nm in size (Shahverdi et al., 2007).

Fourier transform infrared spectroscopy (FTIR) showed an absorbance peak at 3270 cm⁻¹ (OH stretch), 2921 cm⁻¹ (C-H stretch) and 1604 cm⁻¹ (C = C stretch) indicating the presence of polyphenols and conjugation in the extracts (Figure 1b). Our results displayed a peak at about 500 nm, which is supported by transmission electron microscopy (TEM) analysis revealing that the NPs are of smaller size (Figure 1c). The absorbance peak confirming the formation of AgNPs.

Additionally, TEM (Figure 1c) images confirmed that the morphology of CcAgNPs is highly variable with a variety of shapes (spherical, longitudinal and irregular). Their size variations are from 12 to 42 nm. Nanoparticle behaviour appears to be a function of their size and shape. Moreover, X-ray diffraction (XRD) (Figure 1d) analysis showed six distinct diffraction peaks. The strong peak of silver (1646.63 and 44.693 nm) followed by two medium peaks at 468.56 and 310.62 nm indicate that the biosynthesized NPs are indeed made up of only silver.

### 2.5 Experimental Animals

Twenty-four (24) pathogen-free, males Sprague Dawley rats weighing 250 ± 20 g were selected for the experimental study. They were kept and maintained under laboratory
conditions of temperature 21.5 - 22 °C, humidity 60 ± 1%, and 12-hour light/dark cycle. They were allowed free access to food (standard pellets) and water. Animals were allowed to acclimatize for seven days in order to avoid causing stress during the experimental period. Experimental protocols and procedures used in this study were approved by the institutional Ethics Committee of the University of KwaZulu-Natal, ethics reference number AREC/074/016D.

2.6 Measurement of Blood glucose

Thereafter, animals were kept under observation. Fasting blood glucose was measured on day 0, 14, 28, 42 and 56. Animals were tested using Accu-chek Active 50 (Roche) blood glucose strips (Dischem, South Africa), with blood collected from the tail vein of the rats at 10 am daily.

2.7 Experimental design

In this experiment, Sprague Dawley rats were randomly assigned into different groups. The following groups of six animals each were treated. **Group A** was rats that received Cc (200 mg/kg), orally, once per day. **Group B** was rats that were administered with a low dosage of CcAgNPs (5 mg/kg), orally, once per day. **Group C** was rats that were administered with a higher dosage of CcAgNPs (10 mg/kg), orally, once per day (Sulaiman et al., 2015). CcAgNPs were dissolved in normal saline and was administered orally, once daily and group D was rats (the control) that also received normal saline (1ml). All administration was done at 10:00 a.m daily for 56 consecutive days, through a rat gavage needle (Daisy and Saipriya, 2012). Body weight was recorded every week in the morning between 8:00 am and 10:00 am using an electronic balance (Zeiss, West Germany (Pty) Ltd; 0.000 g). After 56 days of administration, all animals were sacrificed using excess Halothane anaesthetic. Blood was then collected via transcardial puncture for biochemistry. liver and kidney tissues were
harvested after a laparotomy and processed for light microscopic studies. In addition, the weights of each kidney and liver were recorded.

2.8 Histopathological examination of kidney and liver tissues

Organs were washed in saline and fixed in 10% neutral buffered formalin for 24 h. Samples were transferred to 70% ethanol (Latendresse et al., 2002). They were then processed using ascending grades of ethyl alcohol to dehydrate the samples, and xylene was used as the clearing agent. Samples were then mounted in molten paraplast at 58 - 62 ºC; 4 - 5μm slices were cut using microtome (Microtome HM 315 microtome, Walldorf, Germany) from the prepared blocks and stained with hematoxylin and eosin (H & E). Sections were viewed and photographed using an Olympus light microscope (Olympus BX51, Tokyo, Japan) with an attached camera (Olympus E-330, Olympus Optical Co. Ltd., Tokyo, Japan).

2.9 Statistical analysis

All results are introduced as the mean ± standard deviation of the mean. Statistical investigations were done utilizing one-way analysis of difference (ANOVA) trailed by Tukey’s post-hoc tests utilizing Graph Pad Prism Version 5. This has empowered statistical comparison between the control and treated groups and statistical significance was acknowledged at P < 0.05. Comparison with P values less than 0.05 were considered to be statistically significant.

3. Results

3.1 Effect of *Cinnamomum cassia* silver nanoparticles (CcAgNPs) on weight of body and vital organs
The oral treatment of rats with low and high doses of CcAgNPs (5 mg/kg and 10 mg/kg) impacted on the body weight of experimental animals compared to the control as well as those treated with Cc. Body weight of experimental rats treated with CcAgNPs at low doses increased significantly compared to those treated with high doses and the control (P < 0.05) (Table 1). In addition, weights of kidneys and liver of rats were not different between those treated at low doses of CcAgNPs and the control as well as the group treated of Cc and this was not statistically significant at P < 0.05.

**3.2 Effect of *Cinnamomum cassia* silver nanoparticles (CcAgNPs) on blood glucose**

It was observed that fasting blood glucose levels of control animals were essentially similar to that of treated animals. Animals in Groups B and C treated with CcAgNPs (5 mg/kg and 10 mg/kg, respectively) showed the same level of fasting blood glucose (Figure 2).

**3.3 Effect of *Cinnamomum cassia* silver nanoparticles (CcAgNPs) on renal function parameters**

It was observed that protein, ketone and haemoglobin levels in the urine of control animals were lower than that of treated animals. Animals in Group B, treated with low doses of CcAgNPs (5 mg/kg), showed a moderate presence of protein, ketone and haemoglobin in the urine, while those in Group C, treated with high doses of CcAgNPs (10 mg/kg) displayed considerable presence of urine markers (Figure 3).
3.4 Effect of *Cinnamomum cassia* silver nanoparticles (CcAgNPs) on the morphology of liver in Sprague Dawley rats

**Histological sections of liver tissue of rats were prepared and stained with the standard H&E technique and presented in Figures 4A-D. Figure 4A showed liver section with outlines of hepatocytes showing nuclei that are clearly visible, central vein appears distorted with loss of sinusoidal lining. Histologic sections of rats treated with 5 mg/kg of CcAgNPs (Figure 4B) shows a distorted cytoarchitecture of hepatocytes, widened sinusoidal spaces and focal congestion in the central veins. There are also infiltrations in the sinusoidal spaces. Rats treated with 10 mg/kg of CcAgNPs (Figure 4C) showed severe and generalised distortions in hepatocellular arrangement with nuclear condensation and pyknosis and areas of vacuolar changes suggestive of loss of liver architectural support/or fibrosis. Sections of the control (Figure 4D) essentially shows normal hepatocytes lining sinusoidal spaces with arrays of radiation towards the central vein. Hepatocytes nuclei are clearly visible and well stained.**

3.5 Effect of *Cinnamomum cassia* silver nanoparticles (CcAgNPs) on the morphology of kidneys of Sprague Dawley rats

**Histological sections of kidney tissue of rats in the group treated with Cc (Figure 5A) showed outline of renal corpuscle with glomeruli and Bowman’s capsular space distinctly showing mild atrophy of glomeruli. The nuclei of collecting tubules are identifiable and mesangial materials delineated showing areas of vacuolar changes. Sections from the kidney of rats treated with 5 mg/kg of CcAgNPs (Figure 5B) exhibited Bowman’s space and glomerular tissue congestion suggestive of necrotic changes. The mesangial tissues also showed nuclei of tubules that appeared deeply stained and interspersed. There was generalised atrophy of glomeruli with fibrillar meshwork in kidney tissues of rats treated with 10 mg/kg CcAgNPs (Figure 5C) compared to control (Figure 5D). The control group (Group 5D) histological
sections appears essentially normal with glomerulus and Bowman’s capsular spaces depicting clear outlines with no detectable pathology. The mesangium is essentially preserved with nuclei of tubule visible and normal.

4. Discussion

Whilst the utilisation of AgNPs for biomedical purposes continues to grow, our insights and understanding of their impacts on living cells and on biochemical structures remains insufficient (Adeyemi et al., 2015; Sulaiman et al., 2015). In this study, we explored the effects of varied doses of CcAgNPs on the liver and kidney of Sprague-Dawley rats following oral treatment. Although animals treated with CcAgNPs showed no obvious signs of distress during the experimental period, there however appeared to be less active and alert compared to the control group. There were no clear differences between the skin colours of the three groups. Abdominal palpations did not reveal any abnormal mass which was confirmed at autopsy.

Data from this study reports changes in the body weight and organ-body weight ratios. These changes in organ-body weight ratios may be suggestive of toxicity subsequent to the administration of CcAgNPs as corroborated by previous researchers who revealed that NPs altered body and organ weights considerably (Sulaiman et al., 2015). Our results contrast the reports of Song et al. (2017) which showed that Cc extract administration significantly decreased body weights, food intakes and serum levels of glucose in obese mice.
While *Cinnamomum cassia* is commonly been used for weight control in traditional medicines, this discordancy may likely be attributed to the diverse experimental design inherent in the two studies as well as other possible mechanistic pathways not clearly understood. Similarly, aqueous extracts from cinnamon have been shown to increase in vitro glucose uptake and glycogen synthesis alongside increased phosphorylation of the insulin receptor. These overall effects are likely to aid in triggering the insulin cascade system with potential hypoglycemic effects (Jarvill-taylor et al., 2001). Our results did not show any significant changes in blood glucose levels between the control group and treated animals neither did CcAgNPs.

As far as the histopathological studies were concerned, they showed degenerative changes and atrophy in renal and hepatic tissues of the rats treated with CcAgNPs in this study and this was exacerbated in the group receiving higher dose of CcAgNPs. Recent studies points to the potential of NPs aggregating in tissues such as the liver which may provoke such alterations observed (Sulaiman et al., 2015) even in liver cells of rats (Hussain et al., 2005).

Whilst some authors propose that AgNPs decrease the action of mitochondria which causes the reduction of accessible vitality for cells (Hussain et al., 2005), it is also possible that damage to the hepatocytes could be attributed to absorption of silver after oral administration (Furchner et al., 1968). More so, Cc is reported to be used for the treatment of diabetes attributable to the phenolics contained therein, it is possible that its beneficial role in diabetic nephropathy treatment is plausible.

Renal markers of injury (ketones, proteins and albumin) as well as qualitative histological evaluations. These derangements were more prominent with the higher dose of CcAgNPs. In agreement with our study, other studies have reported toxic side effects on the
renal tissue which subsequently impacted on renal function (Vasanth and Kurian, 2017) but does not agree with studies by Luo et al. (2013) and Yan et al. (2015) possibly due to the fact that refined active compounds were tested directly or perhaps due to the differences in the experimental design as some were tested on diabetic states.

Although our study did not report antioxidant markers, Cc has been reported to be rich in type A polyphenols demonstrated to be responsible for improvements in fasting glucose even in clinical trials subjects (Anderson et al., 2008). The extract has also shown significant ameliorative role on the antioxidant system in response to elevated levels of titanium dioxide nanoparticles or titanium dioxide bulk salt-induced oxidative stress with restoration of the histological damages in rat liver treated with titanium dioxide nanoparticles or titanium dioxide bulk salt (Shakeel et al., 2017).

5. Conclusion

Our findings revealed that biosynthesized silver nanoparticles using extracts from *Cinnamomum cassia* (CcAgNPs) caused injury to vital organs such as liver and kidney tissues, in normal healthy rats. The toxic effects appear related to the internal deposition of AgNPs which in turn appeared dose-related. It is recommended that detailed immunological and electron microscopic evaluations of the tissues be carried out alongside other markers of liver/kidney injuries (biochemical assays for enzymes) in order to clearly establish specific alterations adjudged with the dosage of CcAgNPs used.
