The relationship of the immune response mediator genes polymorphic variants with the methotrexate efficacy in juvenile idiopathic arthritis

Abstract

Background/aim: The aim of the study was to analyze the relationship of the immune response mediator genes polymorphic loci (TNFA rs1800629, LTA rs909253, IL1B rs16944, IL2-IL21 rs6822844, IL2RA rs2104286, IL6 rs1800795, IL10 rs1800872, MIF rs755622, CTLA4 rs3087243, NFKB1 rs28362491, PTPN22 rs2476601, PADI4 rs2240336) variants with the methotrexate efficacy in juvenile idiopathic arthritis (JIA).

Materials and methods: The study included 274 JIA patients from the Republic of Bashkortostan, Russia. Achieving the American College of Rheumatology Pediatric 30 (ACR Pedi 30) response was regarded as the presence of the response to methotrexate (otherwise – as the absence), while achieving clinical remission on medication (Wallace et al., 2011) – as the sufficient response (otherwise – as the insufficient). Genotyping was conducted by the real-time polymerase chain reaction.

Results: Associations with an altered risk of the non-response to methotrexate in JIA were observed for the alleles/genotypes of the loci IL10 rs1800872 (in girls) and NFKB1 rs28362491 (in girls); with an altered risk of the insufficient response to methotrexate in JIA – for the alleles/genotypes of the loci IL1B rs16944 (in boys), CTLA4 rs3087243 (in boys), NFKB1 rs28362491 (in girls) and the haplotype TNFA rs1800629*A - LTA rs909253*G (in girls).

Conclusion: As a result of the study the relationship of the alleles/genotypes of the IL1B rs16944, IL10 rs1800872, CTLA4 rs3087243, NFKB1 rs28362491 polymorphic loci and the TNFA rs1800629*A - LTA rs909253*G haplotype with the methotrexate efficacy in JIA was established (taking into account the differences by sex).
Key words: Juvenile idiopathic arthritis, polymorphic loci, methotrexate efficacy, predictors

1. Introduction

Juvenile idiopathic arthritis (JIA) is the most common childhood rheumatic disease, which begins before the age of 16 and is characterized by arthritis persisting at least 6 weeks [1, 2, 3]. The JIA diagnosis is entirely based on the clinical features, and the generally accepted disease classification is the International League of Associations for Rheumatology (ILAR) classification [1].

Being a chronic, steadily progressive disease, JIA can lead to short-term and long-term disability [2]. So, early and effective therapy is crucial for preventing JIA complications and patients’ disability [3, 4, 5, 6, 7]. Methotrexate is the most widely used disease-modifying anti-rheumatic drug in the JIA treatment [4]. Methotrexate was first described as the antimetabolite of folic acid and was used in the field of oncology, but the mechanism of its action in rheumatology is still poorly understood [8]. The anti-inflammatory effects of methotrexate in JIA may be mediated by additional to folate antagonism mechanisms, such as adenosine release, inhibition of spermine/spermidine production and/or alteration of cellular redox state [9]. It has been shown that methotrexate may directly or indirectly affect the expression and/or secretion of the various immune response mediators involved in the pathogenesis of JIA and other autoimmune diseases, including cytokines (such as tumour necrosis factor alpha (TNFα), interleukin 1 (IL1), IL2, IL6, IL10), nuclear factor kappa B (NFkB), cytotoxic T-lymphocyte associated protein 4 (CTLA4) and others [10, 11, 12, 13].
Nevertheless, the response to therapy varies among the JIA patients, and the identifying of early predictors of the methotrexate efficacy is highly relevant [4, 7]. Currently, a search for the genetic predictors of the methotrexate efficacy in JIA is underway. The most promising are polymorphic variants of genes involved in the methotrexate metabolic pathway or genes, whose expression changes under the methotrexate effect, as well as a number of markers identified in the genome-wide association study (GWAS) [4, 9, 14, 15, 16]. In addition, the relationship can be assumed between the methotrexate efficacy and the polymorphic variants of other genes encoding proteins, presumably playing an important role in the JIA pathogenesis, including interleukin 2 receptor subunit alpha (IL2Rα), lymphotoxin alpha (LTα), macrophage migration inhibitory factor (MIF), protein tyrosine phosphatase non-receptor type 22 (PTPN22), peptidyl arginine deiminase 4 (PADI4) [17, 18, 19].

Considering the above, the search for the predictors of the JIA patients’ response to methotrexate among some polymorphic variants of genes, which products are involved in the pathogenesis of the autoimmune diseases and are the potential targets for the methotrexate exposure, seems appropriate. Identification of these markers may provide an opportunity to timely predict the JIA therapy efficacy, to determine an adequate treatment strategy and to prevent the development of the disease complications [3, 4, 5, 6, 7]. So, the aim of the study was to analyze the relationship of the immune response mediator genes polymorphic loci (TNFA rs1800629, LTA rs909253, ILIB rs16944, IL2-IL21 rs6822844, IL2RA rs2104286, IL6 rs1800795, IL10 rs1800872, MIF rs755622, CTLA4 rs3087243, NFKB1 rs28362491, PTPN22 rs2476601, PADI4 rs2240336) variants with the methotrexate efficacy in JIA.
A case-control study was conducted. The study was approved by the expert council on biomedical ethics of Bashkir State Medical University (Ufa, Russia).

The study included 274 JIA patients treated with methotrexate. Parents of all patients signed the voluntary informed consent. All patients were residents of the Republic of Bashkortostan and were examined and treated in the cardio-rheumatological department of the Republican Children's Clinical Hospital (Ufa, Russia) in 2011-2017. The median age of the patients was 8.69 (4.82; 12.80) years; the ratio of boys / girls was 31.75% / 68.25%. The JIA diagnosis was established according to the International League of Associations for Rheumatology (ILAR) criteria [1]. According to the ILAR criteria, the following JIA subtypes were presented: systemic arthritis (n=25 (9.12%)), rheumatoid factor positive polyarthritis (n=5 (1.82%)), rheumatoid factor negative polyarthritis (n=76 (27.74%)), persistent oligoarthritis (n=77 (28.10%)), extended oligoarthritis (n=41 (14.96%)), enthesitis related arthritis (n=26 (9.49%)), psoriatic arthritis (n=8 (2.92%)), undifferentiated arthritis (n=16 (5.84%)).

Achieving the American College of Rheumatology Pediatric 30 (ACR Pedi 30) response was regarded as the presence of the response to methotrexate (otherwise – as the absence), while achieving clinical remission on medication (Wallace et al., 2011) – as the sufficient response (otherwise – as the insufficient) [5, 20, 21, 22]. Evaluation of the presence of the response to methotrexate was performed in patients who received the therapy for at least 3 months, and the sufficiency of the response was evaluated in patients who received the therapy for at least 12 months.
2.2. Genotyping

DNA isolation from the lymphocytes of the whole blood samples was performed using a standard phenol-chloroform method [23]. Genotyping of all the patients for the 12 polymorphic loci (TNFA rs1800629, LTA rs909253, IL1B rs16944, IL2-IL21 rs6822844, IL2RA rs2104286, IL6 rs1800795, IL10 rs1800872, MIF rs755622, CTLA4 rs3087243, NFKB1 rs28362491, PTPN22 rs2476601, PADI4 rs2240336) was conducted by the real-time polymerase chain reaction (StepOnePlus™ Real-Time PCR System, Applied Biosystems, USA). Sequence-specific primers and allele-specific probes were designed and synthesized by the "DNK-syntez" company (Russia).

2.3. Statistical analysis

Statistical processing of the results was carried out using Microsoft Excel, SNPStats, R v.3.4.2 (R Core Team, 2017), PowerMarker v.3.25, STATISTICA v.10 (StatSoft, Inc.) [24, 25, 26].

To compare the genotype and allele frequencies in the studied groups the two-tailed Fisher's Exact test was used. A similar analysis was also performed separately for boys and girls. The multiple testing correction of the p-values was carried out by applying the permutation test with $10^4$ permutes ($p_{cor}$) [24, 27]. The odds ratio (OR) with the Baptista-Pike exact conditional 95% confidence interval (95% CI) were also calculated [28].

The haplotypes of the TNFA rs1800629 and LTA rs909253 polymorphic loci, located in the same cluster on chromosome 6, have also been studied as the potential predictors of the methotrexate efficacy in JIA, since the linkage disequilibrium for these loci was almost complete ($D' = 0.9989$, $p=0.000$). The association between the TNFA rs1800629 -
LTAr909253 loci haplotypes and the methotrexate efficacy in JIA was analyzed using the logistic regression method [25].

The analysis of the inheritance models (co-dominant – each genotype can give a different and non-additive risk; dominant – one copy of the variant allele is enough to change the risk; recessive – two copies of the variant allele are necessary to change the risk; over-dominant – heterozygous genotype is compared to a pool of both homozygous genotypes; log-additive – each copy of the variant allele changes the risk in an additive form) was carried out using the logistic regression method, and the selection of the best one – using the Akaike's Information Criterion. The inheritance model with the lowest Akaike's Information Criterion value was considered as the model that best fits the data [25].

In all the cases the results were considered statistically significant at p<0.05.

3. Results

3.1. The study of the predisposition to the absence of the response to methotrexate in JIA

When studying the IL10 rs1800872 polymorphic locus, no predictors of the absence of the response to methotrexate were found in the whole JIA group, as well as in boys with JIA (p>0.1) (Table 1). At the same time, in girls with JIA, the frequency of the IL10 rs1800872*A allele was significantly higher, and of the IL10 rs1800872*CC genotype – significantly lower in the absence of the response to methotrexate than in its presence (*A: 38.16% vs. 24.81%, p=0.029, p_{cor}=0.027, OR=1.87, 95% CI 1.069-3.162; *CC: 36.84% vs. 57.36%, p=0.028, p_{cor}=0.029, OR=0.434, 95% CI 0.215-0.932, respectively). The dominant model of inheritance reflected the results better than the
Analysis of the \textit{NFKB1} rs28362491 polymorphic locus showed, that the \textit{NFKB1} rs28362491*DD genotype was significantly more common, and the \textit{NFKB1} rs28362491*I allele was significantly less common in JIA patients with the absence of the response to methotrexate than in those with its presence (*DD: 31.03\% vs. 13.26\%, \(p=0.005\), \(p_{\text{cor}}=0.004\), OR=2.944, 95\% CI 1.484-5.938; *I: 48.28\% vs. 59.94\%, \(p=0.031\), \(p_{\text{cor}}=0.033\), OR=0.624, 95\% CI 0.410-0.944, respectively). After stratification based on the sex of the patients, similar significant differences for the \textit{NFKB1} rs28362491*DD genotype were found only in girls with JIA (\(p=0.017\), \(p_{\text{cor}}=0.017\), OR=2.846, 95\% CI 1.253-6.483), and only a similar trend was observed in boys with JIA (\(p_{\text{cor}}=0.085\)), which is probably due to the smaller sample size. The best inheritance model turned out to be the recessive (DD vs. II+ID, \(p=0.0032\) and \(p=0.018\) in JIA as a whole and in girls, respectively).

For the alleles and genotypes of the \textit{TNFA} rs1800629, \textit{LTA} rs909253, \textit{IL1B} rs16944, \textit{IL2}-\textit{IL21} rs6822844, \textit{IL2RA} rs2104286, \textit{IL6} rs1800795, \textit{MIF} rs755622, \textit{CTLA4} rs3087243, \textit{PTPN22} rs2476601, \textit{PADI4} rs2240336 polymorphic loci, as well as haplotypes of the \textit{TNFA} rs1800629 - \textit{LTA} rs909253 loci, no associations were observed with the considered trait (\(p>0.05\)).

When studying the \textit{PADI4} rs2240336 polymorphic locus, a borderline significance level tendency was observed for the increase of the proportion of the \textit{PADI4} rs2240336*GA genotype and the decrease of the proportion of the \textit{PADI4} rs2240336*GG genotype in JIA patients with the absence of the response to methotrexate (*GA: \(p_{\text{cor}}=0.053\) and *GG: \(p_{\text{cor}}=0.053\), respectively). However, the significant results were obtained for the dominant model as the best model of inheritance (GA+AA vs. GG, \(p=0.032\)). In the
similar sex-stratified analysis, a tendency was observed in boys with JIA for the rarer occurrence of the *PADI4* rs2240336*GG* genotype in the case of the absence of the response to methotrexate (*p*~cor~ =0.091).

It was also noted, that in the case of the absence of the response to methotrexate in patients with JIA, the *IL2-IL21* rs6822844*TT* and *LTA* rs909253*AG* genotypes were insignificantly more common (*IL2-IL21* rs6822844*TT*: *p*~cor~ =0.054, *LTA* rs909253*AG*: *p*~cor~ =0.098), and the statistically significant results were obtained for the *IL2-IL21* rs6822844 locus when testing the recessive model of inheritance (*TT* vs. *GG+GT*, *p*=0.017).

### 3.2. The study of the predisposition to the insufficient response to methotrexate in JIA

Analysis of the *IL1B* rs16944 polymorphic locus showed a tendency towards a rarer occurrence of the *IL1B* rs16944*CC* genotype in JIA patients with the insufficient response to methotrexate than in those with the sufficient (37.88% vs. 50.00%, respectively, *p*~cor~ =0.094) (Table 2). After stratification by sex, it turned out that boys with JIA, who did not achieve clinical remission on medication with the methotrexate therapy, had a significantly increased proportion of the *IL1B* rs16944*T* allele (41.86% vs. 22.00%, *p*=0.025, *p*~cor~ =0.024, OR=2.553, 95% CI 1.195-5.410, in comparison with those who achieved, respectively). The log-additive model of inheritance reflected the results most successfully (*2TT+CT* vs. *CC*, *p*=0.036). At the same time, there were no significant differences by the studied trait in girls with JIA (*p*>0.1).

For the alleles and genotypes of the *CTLA4* rs3087243 locus, associations with the insufficient response to methotrexate in the general JIA group and in girls with JIA have
not been established (p>0.1). At the same time, in boys with JIA with the insufficient response to methotrexate the \textit{CTLA4} rs3087243*GA genotype and the \textit{CTLA4} rs3087243*A allele were significantly more common, and the \textit{CTLA4} rs3087243*GG genotype was significantly less common, than in those with the sufficient response (*GA: 53.49% vs. 24.00%, p=0.023, p_{cor}=0.022, OR=3.642, 95% CI 1.188-11.379; *A: 38.37% vs. 20.00%, p=0.035, p_{cor}=0.036, OR=2.491, 95% CI 1.128-5.553; *GG: 34.88% vs. 68.00%, p=0.012, p_{cor}=0.013, OR=0.252, 95% CI 0.094-0.733, respectively). The dominant model of inheritance described the results better than the others (GA+AA vs. GG, p=0.0078).

Analysis of the \textit{NFKB1} rs28362491 polymorphic locus showed, that in JIA patients with the insufficient response to methotrexate the \textit{NFKB1} rs28362491*DD genotype was significantly more common, and the \textit{NFKB1} rs28362491*ID genotype was significantly less common, than in those with the sufficient response (*DD: 28.03% vs. 12.50%, p=0.010, p_{cor}=0.011, OR=2.726, 95% CI 1.306-5.568; *ID: 38.64% vs. 62.50%, p=0.001, p_{cor}=0.0008, OR=0.378, 95% CI 0.213-0.675, respectively). However, after stratification by sex, the same associations were observed only in girls with JIA (*DD: p=0.022, p_{cor}=0.024, OR=3.015, 95% CI 1.192-7.700; *ID: p=0.003, p_{cor}=0.003, OR=0.342, 95% CI 0.175-0.672, respectively). The best model of inheritance turned out to be the over-dominant (ID vs. II+DD, p=0.0007 and p=0.0022 in the general JIA group and in girls with JIA, respectively).

For the separate variants of the \textit{TNFA} rs1800629 and \textit{LTA} rs909253 polymorphic loci, no associations with the insufficient response to methotrexate in JIA were found (p>0.05). There was only a tendency towards an increase of the \textit{TNFA} rs1800629*GG genotype proportion and a decrease of the \textit{TNFA} rs1800629*GA genotype proportion in
JIA patients, who did not achieve clinical remission on medication with the methotrexate therapy ($p_{\text{corr}}=0.096$; the *AA genotype was absent in this sample). After stratification by sex, a similar trend for the $TNFA \text{rs1800629}^{*}\text{GG}$ and $*\text{GA}$ genotypes was observed and even increased only in girls with JIA ($p_{\text{corr}}=0.081$).

A study of the haplotypes of the $TNFA \text{rs1800629}$ and $LTA \text{rs909253}$ loci showed a tendency towards a rarer occurrence of the A-G haplotype in JIA patients with the insufficient response to methotrexate than in those with the sufficient (7.20% vs. 11.87%, respectively, $p=0.082$). In the similar sex-stratified analysis, these differences for the A-G haplotype increased and reached the statistical significance level, but only in girls with JIA ($p=0.046$, OR=0.41, 95% CI 0.18-0.98).

For the alleles and genotypes of the $IL2$-$IL21$ rs6822844, $IL2RA$ rs2104286, $IL6$ rs1800795, $IL10$ rs1800872, $MIF$ rs755622, $PTPN22$ rs2476601, $PADI4$ rs2240336 loci associations with the insufficient response to methotrexate were not observed ($p>0.1$).

### 4. Discussion

As a result of the study, the predictors of the methotrexate efficacy in JIA were established. Associations with an altered risk of the non-response to methotrexate in JIA were observed for the alleles/genotypes of the loci $IL10$ rs1800872 (in girls) and $NFKB1$ rs28362491 (in girls); with an altered risk of the insufficient response to methotrexate in JIA – for the alleles/genotypes of the loci $IL1B$ rs16944 (in boys), $CTLA4$ rs3087243 (in boys), $NFKB1$ rs28362491 (in girls) and the haplotype $TNFA$ rs1800629*$A$ - $LTA$ rs909253*$G$ (in girls) (Table 3).

According to the available data, the genetic markers considered in this work have not been previously studied for the associations with the methotrexate efficacy in JIA.
It has been shown, that the methotrexate treatment reduces the TNFα, IL1β, and IL6 production and increases the IL10 expression in the synovial tissue of rheumatoid arthritis patients [12]. At the same time, Pawlik et al. (2006) established the interrelation of a number of the cytokine genes polymorphic loci variants with the level of phytohemagglutinin-stimulated secretion of the corresponding products by peripheral blood mononuclear cells of healthy volunteers from Poland [10]. In particular, there was a significant increase of the levels of IL6 in the IL6 rs1800795*GG homozygotes (in comparison with the IL6 rs1800795*CC homozygotes), of IL10 – in homozygotes for the GCC haplotype of the IL10 gene rs1800896, rs1800871 and rs1800872 loci (compared to the ATA/ATA, ACC/ACC, ACC/ATA genotypes), of TNFα – in the TNFA rs1800629*GA heterozygotes (in comparison with the TNFA rs1800629*GG homozygotes). The identified differences remained even after the treatment of the cell culture with increasing doses of methotrexate, but not dexamethasone [10]. Considering that IL10 is one of the main anti-inflammatory mediators [11], these data are partially consistent with the results of the present work, where the association of the IL10 rs1800872*A allele with an increased risk of the non-response to methotrexate in girls with JIA was shown. At the same time, TNFα has a powerful pro-inflammatory effect [11], but in the present work it was shown, that the TNFA rs1800629*A allele in the TNFA rs1800629*A - LTA rs909253*G haplotype acts as a protective marker in relation to the insufficient response to methotrexate in girls with JIA. This fact may be due to the presence of the LTA rs909253*G allele, since Pociot et al. (1991) showed, that the level of the TNFα and IL1β production by lipopolysaccharide- and phytohemagglutinin-stimulated monocytes was significantly lower in healthy carriers of the LTA rs909253*AG genotype than in those with the LTA rs909253*AA genotype [29]. Given
the sexual specificity of the established association, it can also be assumed that the observed contradictions are related to the peculiarities of the immune response regulation in males and females, leading to the differences in the secretion of cytokines and other mediators [30].

The data on the relationship of the *IL1B* rs16944 polymorphic loci variants with the *IL1B* expression are extremely contradictory. In particular, analyzing the *IL1B* gene haplotypes, Chen et al. (2006) showed the association of the *IL1B* rs16944*T* allele with an increased transcriptional activity of the reporter gene when stimulated by lipopolysaccharide- and phorbol-12-myristate-13-acetate [31], and Wen et al. (2006) – with a decreased one when stimulated only by lipopolysaccharide [32]. In addition to the experimental features, these differences can also be associated with the samples characteristics, in particular with the sex ratio, since in the present work it was shown that the *IL1B* rs16944*T* allele increases the risk of the insufficient response to methotrexate only in boys with JIA. It should also be noted that the relationship of the *IL1B* rs16944*TT* genotype with the non-achieving of the ACR Pedi 70 response to etanercept in JIA was previously established, which is important to consider when selecting the second-line therapy for these patients [33].

*CTLA4* is a member of the immunoglobulin-related receptors family and is believed to play an important role in mediating the suppressive function of regulatory T cells [34]. Cribbs et al. (2015) showed that the methotrexate treatment of rheumatoid arthritis patients enhances the reduced *CTLA4* expression in regulatory T cells and restores their defective suppressor function [13]. Moreover, Kasela et al. (2017) found that the *CTLA4* rs3087243*A* allele is associated with the higher *CTLA4* expression levels in the CD4+ and CD8+ T cells [35]. It can be assumed that the presence of the *CTLA4* rs3087243*A*
allele in boys with JIA indicates the predominance of other pathogenetic mechanisms that are not associated with the reduced CTLA4 expression, which determines the absence of the important therapeutic target for the methotrexate exposure and, as a result, its insufficient efficacy in this group of patients.

An important role in the regulation of inflammation, cell survival and proliferation is played by NFκB – a family of transcription factors (RelA (p65), cRel, RelB, NFκB1 (p50 and its precursor p105), and NFκB2 (p52 and its precursor p100)), which functions as various hetero- or homodimers [12, 36, 37]. One of the key members of this family is p50 encoded by the NFKB1 gene. It should be noted that p50 has opposite effects in the hetero- / homodimeric forms. Thus, p50/p50 homodimers have an anti-inflammatory effect, inhibiting the transcription of pro-inflammatory cytokine genes, including TNFA, and enhancing the IL10 gene transcription. At the same time, p50/p65 heterodimers exhibit pro-inflammatory properties and stimulate the transcription of the corresponding cytokine genes, including TNFA [36, 37, 38]. Methotrexate has been shown to inhibit the p65 phosphorylation and thereby to downregulate the expression of TNFA [39, 40].

It is assumed that the NFKB1 rs28362491*D allele may cause a decrease in the NFKB1 expression and, accordingly, the p50 production; the decrease in the p50/p50 homodimer levels most likely exceeds the decrease in the p50/p65 heterodimer levels, which leads to the increased pro-inflammatory cytokine production in these patients [37, 38, 41]. In addition, the decrease in the p50/p65 heterodimer formation may lead to the partial loss of an important therapeutic target for the methotrexate exposure, which overall mediates its subsequent inefficiency. At the same time, an increased pro-inflammatory cytokine production in the NFKB1 rs28362491*D allele carriers may suggests a good effect of an anti-cytokine therapy. This hypothesis is confirmed by the
data of Nazarova et al. (2018), according to which the NFKB1 rs28362491*D allele reduces the risk of non-achieving the ACR Pedi 70 response to etanercept in JIA patients [33]. At the same time, in the present work it was shown, that the NFKB1 rs28362491*DD genotype marks an increased susceptibility to the non-response to methotrexate in JIA (in girls). These data are of particular interest in terms of predicting the efficacy of JIA therapy: they allow to identify the risk group for the non-response to methotrexate and at the first signs of an unfavorable prognosis realization or initially to recommend the strengthening of therapy by prescribing etanercept for this group.

The potential limitations of this research are the relatively small number of the studied polymorphic genes variants, as well as the possible ethnic specificity of the identified associations. To confirm the obtained data, replicative studies on different ethnicity samples are required, as well as additional immunological studies to assess the true causes underlying the observed associations. In addition, the prediction of the JIA therapy efficacy using the genetic testing is quite expensive, so the implementation of this method in low economic communities may be rather difficult.

5. Conclusion

This study was aimed to identify the potential predictors of the JIA patients’ response to methotrexate among some of the immune response mediator genes polymorphic loci (TNFA rs1800629, LTA rs909253, IL1B rs16944, IL2-IL21 rs6822844, IL2RA rs2104286, IL6 rs1800795, IL10 rs1800872, MIF rs755622, CTLA4 rs3087243, NFKB1 rs28362491, PTPN22 rs2476601, PADI4 rs2240336) variants. As a result of the study the relationship of the alleles/genotypes of the IL1B rs16944, IL10 rs1800872, CTLA4 rs3087243, NFKB1 rs28362491 polymorphic loci and the TNFA rs1800629*A - LTA
rs909253*G haplotype with the methotrexate efficacy in JIA was established (taking into account the differences by sex). Associations for the IL1B rs16944 and NFKB1 rs28362491 polymorphic loci variants seem to be the most promising, since they allow to evaluate the efficacy prognosis simultaneously for two the most widely used disease-modifying anti-rheumatic drugs in the JIA treatment: methotrexate and etanercept. If confirmed in replicative studies, the established markers might be used for the early prediction of the JIA therapy efficacy and the timely appointment of an adequate medication, which is crucial for preventing the disease complications.
